You said:

I'm working on an enterprise-grade data ingestion and ETL pipeline using Node.js, JavaScript and MySQL. Before implementation, help me break down the requirements into functional components, identify challenges, and suggestt a good architecture. Avoid introducing unnecessary technologies.

ChatGPT said:

You said:

How should I design an ingestion layer that supports multiple file formats, malformed files, duplicate file deliveries, and reproducible processing?

ChatGPT said:

You said:

What database schema would you recommend for tracking pipeline execution history, processed files, curated customers, transactions, and rejected records

ChatGPT said:

You said:

For the ingestion architecture, my decisions are: record failure policy = partial; initial file format support = both. Please refine the architecture and implementation plan accordingly.

this

ChatGPT said:

You said:

yes,the `processed_files` table is designed to maintain file level idempotency and processing history.

ChatGPT said:

You said:

I have been working on an Enterprise Data Ingestion and ETL Pipeline using Node.js, Express.js and MySQL.

I want you to help me write a README.md for this project. I'll explain what I have implemented so far.

The pipeline takes CSV and JSON files from an incoming directory, processes them, validates the records, transforms the data into a consistent structure and loads valid records into MySQL.

I have also implemented file-level idempotency using SHA-256 hashing and a processed_files table to track processed files and their history.

For record-level deduplication, the pipeline identifies identical transactions and skips them. If the same transaction ID comes with different business values, it identifies the conflict instead of blindly overwriting the existing record.

Invalid records are stored separately in the rejected zone, while valid records continue to be processed. The pipeline also generates execution reports containing processing statistics and reconciliation details.

After successful processing, the original files are moved from the incoming directory to the processed

directory.

I have also written automated tests covering ingestion, parsing, validation, transformation, idempotency, duplicate transactions, conflicting records and edge cases.

Please turn this into a professional but natural-looking README. Keep the language simple and realistic, like something an engineering student or fresher would write for a project on GitHub.

Don't exaggerate the features or claim anything that I haven't implemented. Include the project overview, architecture, features, tech stack, folder structure, setup instructions, how to run the pipeline, database configuration and testing instructions.

Avoid generic AI-sounding phrases and unnecessary buzzwords. Make it technically accurate and easy for another developer to understand.
